1 Overview

This software module controls the ADC on the F/C280x devices. It sets up the ADC in synchronous mode at CNT_zero event of the time-base of ePWM1, to convert one channel, and to make it available in a variable in the application.

Figure 1. Synchronous conversion, one channel ADC Driver

2 Module Properties

This section describes module properties, such as compatible devices, components, invocation etc. The ADC1SYNC_DRV module has the following dependencies:

<table>
<thead>
<tr>
<th>Module</th>
<th>Dependency</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPU dependency</td>
<td>C28x</td>
</tr>
<tr>
<td>Device dependency</td>
<td>x2801 / x2806 / x2808 members only</td>
</tr>
</tbody>
</table>

Table 1. ADC1SYNC_DRV module dependencies

The ADC1SYNC_DRV module has the following components:

<table>
<thead>
<tr>
<th>Component</th>
<th>Present</th>
</tr>
</thead>
<tbody>
<tr>
<td>C-based initialization</td>
<td>Yes</td>
</tr>
<tr>
<td>ASM interrupt initialization</td>
<td>Yes</td>
</tr>
<tr>
<td>ASM runtime macro</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Table 2. ADC1SYNC_DRV module components

The ADC1SYNC_DRV module has the following miscellaneous properties:

<table>
<thead>
<tr>
<th>Property name</th>
<th>Property value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Multiple instance support</td>
<td>No</td>
</tr>
<tr>
<td>Reentrant</td>
<td>No</td>
</tr>
<tr>
<td>Accessible from ‘C’ environment</td>
<td>Yes</td>
</tr>
<tr>
<td>Full configuration from ‘C’ environment</td>
<td>Yes</td>
</tr>
<tr>
<td>Input / Output connection</td>
<td>Pointer to signal net.</td>
</tr>
</tbody>
</table>

4 Module API Description

This module has three executable code components, as described in Table 2. Each of these components is described in this section.

4.1 ADC1SYNCCnf

Function Name: ADC1SYNCCnf

Prototype: void ADC1SYNCCnf(int mCh, int AcqWidth);

Return value: None.

Preconditions: The following preconditions must be satisfied:

The ADC module clock must be enabled in the PCLKCR0 register.

The ADC1SYNCCnf function is called from the C environment, and performs driver configuration, including configuration of ADC registers.

☐ mCh: Channel to be converted to output 0.

Valid Range: 0-15, corresponding to ADC channels A0-A7 and B0-B7. The channel selection is shown in Table 7 below.

† The xyz represents the version number directory level. For instance, a 1.00 release would have v100 in its directory path, and v210 would indicate a release 2.10.
AcqWidth: Specifies the acquisition prescaler in clock cycles.

<table>

</tr>
<tr>
<td>15</td>
<td>ADCINB7</td>
</tr>
</tbody>
</table>

*Table 7. ADC1SYNC_DRV channel selection*

Example: Call the ADC1SYNCCnf function to initialize EPWM1 module.

```c
// Set up conversion of channels 0 with acq prescaler at 2 clocks
ADC1SYNCCnf(0,2);
```

4.2 ADC1SYNC_DRV_INIT

Function Name: ADC1SYNC_DRV_INIT

Prototype: ADC1SYNC_DRV_INIT

Return value: None.

Preconditions: The following preconditions must be satisfied:

- The ADC module clock must be enabled in the PCLKCR0 register, and
- The C language init routine must be called.

This function is the assembler initialization macro, and must be called in addition to the C language initialization routine, for proper operation of the runtime macro routine. This initialization routine must be executed as part of an assembler initialization routine. This macro routine...
declares variables, initializes variables to known values, and sets up constants for the runtime macro routines.

Example: Call the ADC1CH_DRV_INIT to initialize the ADC1CH_DRV module.

```c
;---------------------------------------------------------
; ISR Initialisation
;---------------------------------------------------------
_ISR_Init: ADC1SYNC_DRV_INIT
LRETR
```

### 4.3 ADC1SYNC_DRV

<table>
<thead>
<tr>
<th>Function Name:</th>
<th>ADC1SYNC_DRV</th>
</tr>
</thead>
<tbody>
<tr>
<td>Prototype:</td>
<td>ADC1SYNC_DRV</td>
</tr>
<tr>
<td>Return value:</td>
<td>None.</td>
</tr>
</tbody>
</table>
| Preconditions: | The following preconditions must be satisfied:  
  - The ADC module clock must be enabled in the PCLKCR0 register.  
  - C language init routine must be called.  
  - The ISR initialization macro ADC1SYNC_DRV_INIT must be instanced and executed in an assembler initialization routine. |

This function is the assembler run time macro, and this creates code that forms a bridge between software and the ADC register hardware output. The output is written to the ADC1CH_Rslt variable.

Example: Call the ADC1SYNC_DRV in an assembler ISR

```c
;---------------------------------------------------------
; Runtime interrupt service routine
;---------------------------------------------------------
_ISR_Run: CONTEXT_SAVE ; call macro
ADC1SYNC_DRV
. . . ; other code
;---------------------------------------------------------
EXIT_ISR: ;Interrupt management before exit
;---------------------------------------------------------
MOVW DP,#ETCLR1>>6
MOV @ETCLR1,#0x01 ; Clear EPWM1 Int flag
;---------------------------------------------------------
; Restore context & return
;---------------------------------------------------------
CONTEXT_REST
IRET
```
5 Usage Example:

![Diagram](image)

Figure 2. Connecting the one channel ADC driver

Step 1. Call the driver configuration function in C (this is one-time pass through code)

```c
ADC1SYNCnf(CH_Am_NO, ACQ_PRESCALER_SETTING);
```

Step 2. Instantiate the INIT macro in assembly (this is one-time pass through code)

```c
; Instantiate the init macro
ADC1SYNC_DRV_INIT
```

Step 3. Instantiate the run time macro in assembly (this is usually looped or ISR code)

```c
; "call" the main macro
ADC1SYNC_DRV
```

Step 4. (optional) Declare “Signal Nets” to “connect” the module to in “C”

```c
int16 AdcValue[1];
; Note AdcValue can be simply an global integer array variable
```

Step 5. Declare the module “Terminal pointers” in “C”

```c
// ADC1SYNC_DRV terminal pointers, external references
extern int16 *ADC1CH_Rslt;
```

Step 6. “Connect” the module terminals to the Signal Nets in “C”.

```c
// ADC1SYNC_DRV connections
ADC1CH_Rslt = &AdcValue[0];

// Note this can be done once during init, or dynamically during
// run time operation, i.e. module connections can be
// re-configured to other Nets as required by the application.
```
