Capitalizing on Intel’s 0.25 µm two-bit-per-cell technology, second generation Intel StrataFlash® memory products provide 2X the bits in 1X the space, with new features for mainstream performance. Offered in 128-Mbit (16-Mbyte), 64-Mbit, and 32-Mbit densities, these devices bring reliable, two-bit-per-cell storage technology to the flash market segment.

Benefits include: more density in less space, high-speed interface, lowest cost-per-bit NOR devices, support for code and data storage, and easy migration to future devices.

Using the same NOR-based ETOX™ technology as Intel’s one-bit-per-cell products, Intel StrataFlash memory devices take advantage of over one billion units of Flash manufacturing experience since 1987. As a result, Intel StrataFlash components are ideal for code and data applications where high density and low cost are required. Examples include networking, telecommunications, digital set top boxes, audio recording, and digital imaging.

By applying FlashFile™ memory family pinouts, Intel StrataFlash memory components allow easy design migrations from existing Word-Wide FlashFile memory (28F160S3 and 28F320S3), and first generation Intel StrataFlash memory (28F640J5 and 28F320J5) devices.

Intel StrataFlash memory components deliver a new generation of forward-compatible software support. By using the Common Flash Interface (CFI) and the Scalable Command Set (SCS), customers can take advantage of density upgrades and optimized write capabilities of future Intel StrataFlash memory devices. Manufactured on Intel® 0.25 micron ETOX™ VI process technology, Intel StrataFlash memory provides the highest levels of quality and reliability.

**Notice**: This document contains information on new products in production. The specifications are subject to change without notice. Verify with your local Intel sales office that you have the latest datasheet before finalizing a design.

<td>Changed Minimum Block Erase time, IOL, ICH, Page Mode and Byte Mode currents. Modified RP# on AC Waveform for Write Operations</td>
</tr>
</tbody>
</table>
| 12/16/99         | -004   | Changed Block Erase time and tAVWH  
Removed all references to 5 V I/O operation  
Corrected Ordering Information, Valid Combinations entries  
Changed Min program time to 211 µs  
Added DU to Lead Descriptions table  
Changed Chip Scale Package to Ball Grid Array Package  
Changed default read mode to page mode  
Removed erase queuing from Figure 10, Block Erase Flowchart |
| 03/16/00         | -005   | Added Program Max time  
Added Erase Max time  
Added Max page mode read current  
Moved tables to correspond with sections  
Fixed typographical errors in ordering information and DC parameter table  
Removed VCCQ1 setting and changed VCCQ1/2 to VCCQ2/3  
Added recommended resistor value for STS pin  
Change operation temperature range  
Removed note that rp# could go to 14 V  
Removed VDL of 0.45 V; Removed VOH of 2.4 V  
Updated ICCR Typ values  
Added Max lock-bit program and lock times  
Added note on max measurements |
| 06/26/00         | -006   | Updated cover sheet statement of 700 million units to one billion  
Corrected Table 10 to show correct maximum program times  
Corrected error in Max block program time in section 6.7  
Corrected typical erase time in section 6.7 |
| 02/15/01         | -007   | Updated cover page to reflect 100K minimum erase cycles  
Updated cover page to reflect 110 ns 32M read speed  
Removed Set Read Configuration command from Table 4  
Updated Table 8 to reflect reserved bits are 1-7; not 2-7  
Updated Table 16 bit 2 definition from R to PSS  
Changed VPENLK Max voltage from 0.8 V to 2.0 V, Section 6.4, DC Characteristics  
Updated 32Mbit Read Parameters R1, R2 and R3 to reflect 110ns, Section 6.5, AC Characteristics–Read-Only Operations  
Updated write parameter W13 (tWHRU) from 90 ns to 500 ns, Section 6.6, AC Characteristics–Write Operations  
Updated Max. Program Suspend Latency W16 (tWHRH1) from 30 to 75 µs, Section 6.7, Block Erase, Program, and Lock-Bit Configuration Performance  |
<p>| 04/13/01         | -008   | Revised Section 7.0, Ordering Information |</p>

Removed byte mode read current row un DC characteristics  
Added ordering information for VF BGA Package  
Minor text edits |
| 03/21/02         | -011    | Changed datasheet to reflect the best known methods  
Updated max value for Clear Block Lock-Bits time  
Minor text edits |
1.0 Introduction

1.1 Document Purpose

This document contains information pertaining to the 3 Volt Intel StrataFlash\textsuperscript{®} Memory device, J3. The purpose of this document is to facilitate the use of this product and describe the features, operations, and specifications of this device.

1.2 Nomenclature

- **AMIN**: AMIN = A0 for x8
  AMIN = A1 for x16
- **AMAX**: 32 Mbit AMAX = A21
  64 Mbit AMAX = A22
  128 Mbit AMAX = A23
- **Block**: A group of flash cells that share common erase circuitry and erase simultaneously
- **Clear**: Indicates a logic zero (0)
- **CUI**: Command User Interface
- **MLC**: Multi-Level Cell
- **OTP**: One Time Programmable
- **PLR**: Protection Lock Register
- **PR**: Protection Register
- **PRD**: Protection Register Data
- **Program**: To write data to the flash array
- **RCR**: Read Configuration Register
- **RFU**: Reserved for Future Use
- **Set**: Indicates a logic one (1)
- **SR**: Status Register
- **SRD**: Status Register Data
- **VPEN**: Refers to a signal or package connection name
- **VPEN**: Refers to timing or voltage levels
- **WSM**: Write State Machine
- **XSR**: eXtended Status Register

1.3 Conventions

- **0x**: Hexadecimal prefix
- **0b**: Binary prefix
- **k (noun)**: 1,000
- **M (noun)**: 1,000,000
- **Nibble**: 4 bits
- **Byte**: 8 bits
- **Word**: 16 bits
- **Kword**: 1,024 words
- **Kb**: 1,024 bits
- **KB**: 1,024 bytes
- **Mb**: 1,048,576 bits
- **MB**: 1,048,576 bytes
2.0 Device Description

2.1 Product Overview

The 0.25 µm 3 Volt Intel StrataFlash® memory family contains high-density memories organized as 16 Mbytes or 8 Mwords (128-Mbit), 8 Mbytes or 4 Mwords (64-Mbit), and 4 Mbytes or 2 Mwords (32-Mbit). These devices can be accessed as 8- or 16-bit words. The 128-Mbit device is organized as one-hundred-twenty-eight 128-Kbyte (131,072 bytes) erase blocks. The 64-Mbit device is organized as sixty-four 128-Kbyte erase blocks while the 32-Mbit device contains thirty-two 128-Kbyte erase blocks. Blocks are selectively and individually lockable in-system. A 128-bit protection register has multiple uses, including unique flash device identification.

The device’s optimized architecture and interface dramatically increases read performance by supporting page-mode reads. This read mode is ideal for non-clock memory systems.

A Common Flash Interface (CFI) permits software algorithms to be used for entire families of devices. This allows device-independent, JEDEC ID-independent, and forward- and backward-compatible software support for the specified flash device families. Flash vendors can standardize their existing interfaces for long-term compatibility.

Scalable Command Set (SCS) allows a single, simple software driver in all host systems to work with all SCS-compliant flash memory devices, independent of system-level packaging (e.g., memory card, SIMM, or direct-to-board placement). Additionally, SCS provides the highest system/device data transfer rates and minimizes device and system-level implementation costs.

A Command User Interface (CUI) serves as the interface between the system processor and internal operation of the device. A valid command sequence written to the CUI initiates device automation. An internal Write State Machine (WSM) automatically executes the algorithms and timings necessary for block erase, program, and lock-bit configuration operations.

A block erase operation erases one of the device’s 128-Kbyte blocks typically within one second—indeed of other blocks. Each block can be independently erased 100,000 times. Block erase suspend mode allows system software to suspend block erase to read or program data from any other block. Similarly, program suspend allows system software to suspend programming (byte/word program and write-to-buffer operations) to read data or execute code from any other block that is not being suspended.

Each device incorporates a Write Buffer of 32 bytes (16 words) to allow optimum programming performance. By using the Write Buffer, data is programmed in buffer increments. This feature can improve system program performance more than 20 times over non-Write Buffer writes.

Individual block locking uses block lock-bits to lock and unlock blocks. Block lock-bits gate block erase and program operations. Lock-bit configuration operations set and clear lock-bits (Set Block Lock-Bit and Clear Block Lock-Bits commands).

The Status Register indicates when the WSM’s block erase, program, or lock-bit configuration operation is finished.
The STS (STATUS) output gives an additional indicator of WSM activity by providing both a hardware signal of status (versus software polling) and status masking (interrupt masking for background block erase, for example). Status indication using STS minimizes both CPU overhead and system power consumption. When configured in level mode (default mode), it acts as a RY/BY# signal. When low, STS indicates that the WSM is performing a block erase, program, or lock-bit configuration. STS-high indicates that the WSM is ready for a new command, block erase is suspended (and programming is inactive), program is suspended, or the device is in reset/power-down mode. Additionally, the configuration command allows the STS signal to be configured to pulse on completion of programming and/or block erases.

Three CE signals are used to enable and disable the device. A unique CE logic design (see Table 3, “Chip Enable Truth Table” on page 16) reduces decoder logic typically required for multi-chip designs. External logic is not required when designing a single chip, a dual chip, or a 4-chip miniature card or SIMM module.

The BYTE# signal allows either x8 or x16 read/writes to the device. BYTE# at logic low selects 8-bit mode; address A0 selects between the low byte and high byte. BYTE# at logic high enables 16-bit operation; address A1 becomes the lowest order address and address A0 is not used (don’t care). A device block diagram is shown in Figure 4 on page 14.

When the device is disabled (see Table 3 on page 16) and the RP# signal is at VCC, the standby mode is enabled. When the RP# signal is at GND, a further power-down mode is enabled which minimizes power consumption and provides write protection during reset. A reset time (tPHQV) is required from RP# switching high until outputs are valid. Likewise, the device has a wake time (tPHWL) from RP#-high until writes to the CUI are recognized. With RP# at GND, the WSM is reset and the Status Register is cleared.

### 2.2 Ballout Diagrams

Intel StrataFlash® Memory is available in three package types. Easy BGA in a 64-ball configuration, along with 56-lead TSOP (Thin Small Outline Package), support all offered densities. A 48-ball VF BGA package supporting the 32 Mbit device is also supported. Figure 1, Figure 2, and Figure 3 show the pinouts.
Figure 1. 3 Volt Intel StrataFlash® Memory Easy BGA Ballout

NOTES:
1. Address A22 is only valid on 64-Mbit densities and above, otherwise, it is a no connect (NC).
2. Address A23 is only valid on 128-Mbit densities and above, otherwise, it is a no connect (NC).
3. Address A24 is only valid on 256-Mbit densities and above, otherwise, it is a no connect (NC).
4. Reserved for Future Use (RFU) signals refer to signals that are reserved by Intel for future device functionality and enhancement.

Figure 2. 3 Volt Intel StrataFlash® Memory 56-Lead TSOP (32/64/128 Mbit) Offers an Easy Migration from the 32-Mbit Intel StrataFlash Component (28F320J5) or the 16-Mbit FlashFile™ Component (28F160S3)
NOTES:
1. A22 exists on 64-, 128- and 256-Mbit densities. On 32-Mbit densities this signal is a no-connect (NC).
2. A23 exists on 128-Mbit densities. On 32- and 64-Mbit densities this signal is a no-connect (NC).
3. A24 exists on 256-Mbit densities. On 32-, 64- and 128-Mbit densities this signal is a no-connect (NC).
4. V\text{CC} = 5 \text{ V} \pm 10\% for the 28F640J5/28F320J5.

NOTES:
1. CE# is equivalent to CE0, and CE1 and CE2 are internally grounded.
2. STS not supported on this package.
3. x8 not supported on this package.

Figure 3. 3 Volt Intel StrataFlash\textsuperscript{®} Memory VF BGA Ballout(32 Mbit)
### 2.3 Signal Descriptions

Table 1 lists the active signals used and provides a description of each.

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Type</th>
<th>Name and Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>A0</td>
<td>INPUT</td>
<td>BYTE-SELECT ADDRESS: Selects between high and low byte when the device is in x8 mode. This address is latched during a x8 program cycle. Not used in x16 mode (i.e., the A0 input buffer is turned off when BYTE# is high).</td>
</tr>
<tr>
<td>D[7:0]</td>
<td>INPUT/OUTPUT</td>
<td>LOW-BYTE DATA BUS: Inputs data during buffer writes and programming, and inputs commands during CUI writes. Outputs array, query, identifier, or status data in the appropriate read mode. Floated when the chip is de-selected or the outputs are disabled. Outputs D[6:0] are also floated when the WSM is busy. Check SR7 to determine WSM status.</td>
</tr>
<tr>
<td>D[15:8]</td>
<td>INPUT/OUTPUT</td>
<td>HIGH-BYTE DATA BUS: Inputs data during x16 buffer writes and programming operations. Outputs array, query, or identifier data in the appropriate read mode; not used for Status Register reads. Floated when the chip is de-selected, the outputs are disabled, or the WSM is busy.</td>
</tr>
<tr>
<td>CE0, CE1, CE2</td>
<td>INPUT</td>
<td>CHIP ENABLES: Activates the device’s control logic, input buffers, decoders, and sense amplifiers. When the device is de-selected (see Table 3 on page 16), power reduces to standby levels. All timing specifications are the same for these three signals. Device selection occurs with the first edge of CE0, CE1, or CE2 that enables the device. Device deselection occurs with the first edge of CE0, CE1, or CE2 that disables the device (see Table 3 on page 16).</td>
</tr>
<tr>
<td>RP#</td>
<td>INPUT</td>
<td>RESET/POWER-DOWN: Resets internal automation and puts the device in power-down mode. RP#-high enables normal operation. Exit from reset sets the device to read array mode. When driven low, RP# inhibits write operations which provides data protection during power transitions.</td>
</tr>
<tr>
<td>OE#</td>
<td>INPUT</td>
<td>OUTPUT ENABLE: Activates the device’s outputs through the data buffers during a read cycle. OE# is active low.</td>
</tr>
<tr>
<td>WE#</td>
<td>INPUT</td>
<td>WRITE ENABLE: Controls writes to the CUI, the Write Buffer, and array blocks. WE# is active low. Addresses and data are latched on the rising edge of the WE# pulse.</td>
</tr>
<tr>
<td>STS</td>
<td>OPEN DRAIN OUTPUT</td>
<td>STATUS: Indicates the status of the internal state machine. When configured in level mode (default mode), it acts as a RY/BY# signal. When configured in one of its pulse modes, it can pulse to indicate program and/or erase completion. For alternate configurations of the STATUS signal, see the Configurations command. Tie STS to VCCQ with a pull-up resistor.</td>
</tr>
<tr>
<td>BYTE#</td>
<td>INPUT</td>
<td>BYTE ENABLE: BYTE# low places the device in x8 mode. All data is then input or output on D[7:0], while D[15:8] float. Address A0 selects between the high and low byte. BYTE# high places the device in x16 mode, and turns off the A0 input buffer. Address A1 then becomes the lowest order address.</td>
</tr>
<tr>
<td>VPEN</td>
<td>INPUT</td>
<td>ERASE / PROGRAM / BLOCK LOCK ENABLE: For erasing array blocks, programming data, or configuring lock-bits. With VPEN ≤ VPENLK, memory contents cannot be altered.</td>
</tr>
<tr>
<td>VCC</td>
<td>SUPPLY</td>
<td>DEVICE POWER SUPPLY: With VCC ≤ VCCO, all write attempts to the flash memory are inhibited.</td>
</tr>
</tbody>
</table>

Figure 4. 3 Volt Intel StrataFlash® Memory Block Diagram
2.5 Memory Map

Figure 5. 3 Volt StrataFlash® Memory Map
3.0 Device Operations

This section provides an overview of device operations. The on-chip Write State Machine (WSM) manages all block-erase and word-program algorithms. The system CPU provides control of all in-system read, write, and erase operations of the device via the system bus.

Device commands are written to the CUI to control all of the flash memory device’s operations. The CUI does not occupy an addressable memory location; it’s the mechanism through which the flash device is controlled.

3.1 Bus Operations

The local CPU reads and writes flash memory in-system. All bus cycles to or from the flash memory conform to standard microprocessor bus cycles.

</tr>
</tbody>
</table>

NOTES:
1. See Table 3 on page 16 for valid CE configurations.
2. OE# and WE# should never be enabled simultaneously.
3. D refers to D[7:0] if BYTE# is low and D[15:0] if BYTE# is high.
4. Refer to DC Characteristics. When VPEN ≤ V_PENL, memory contents can be read, but not altered.
5. X can be VIL or VIH for control and address signals, and V_PENL or VPEN for V_PEN. See DC Characteristics for V_PENL and VPEN voltages.
6. In default mode, STS is V_OH when the WSM is executing internal block erase, program, or lock-bit configuration algorithms. It is V_OH when the WSM is not busy, in block erase suspend mode (with programming inactive), program suspend mode, or reset/power-down mode.
7. High Z will be V_OH with an external pull-up resistor.
8. See Section 4.2, “Read Identifier Codes” on page 19 for read identifier code data.
9. See Section 4.4, “Read Query/CFI” on page 22 for read query data.
10. Command writes involving block erase, program, or lock-bit configuration are reliably executed when VPEN = VPENH and V_CC is within specification.

</tbody>
</table>

NOTE: For single-chip applications, CE2 and CE1 can be strapped to GND.

3.1.1 Read Mode

To perform a bus read operation, CE# (please refer to Table 3 on page 16) and OE# must be asserted. CE# is the device-select control; when active, it enables the flash memory device. OE# is the data-output control; when active, the addressed flash memory data is driven onto the I/O bus. For all read states, WE# and RP# must be de-asserted. See Section 11.1, “Read Operations” on page 37. Refer to Section 4.0, “Read Operations” on page 19 for details on reading from the flash array, and refer to Section 8.0, “Special Modes” on page 30 for details regarding all other available read states.

3.1.2 Write

Writing commands to the Command User Interface enables various modes of operation, including the reading of device data, query, identifier codes, inspection and clearing of the Status Register, and, when $V_{PEN} = V_{PENH}$, block erasure, program, and lock-bit configuration.

The Block Erase command requires appropriate command data and an address within the block to be erased. The Byte/Word Program command requires the command and address of the location to be written. Set Block Lock-Bit commands require the command and block within the device to be locked. The Clear Block Lock-Bits command requires the command and address within the device.

The CUI does not occupy an addressable memory location. It is written when the device is enabled and WE# is active. The address and data needed to execute a command are latched on the rising edge of WE# or the first edge of CE0, CE1, or CE2 that disables the device (see Table 3 on page 16). Standard microprocessor write timings are used.

3.1.3 Output Disable

With OE# at a logic-high level ($V_{IH}$), the device outputs are disabled. Output signals $D[15:0]$ are placed in a high-impedance state.
3.1.4 **Standby**

CE0, CE1, and CE2 can disable the device (see Table 3 on page 16) and place it in standby mode which substantially reduces device power consumption. D[15:0] outputs are placed in a high-impedance state independent of OE#. If deselected during block erase, program, or lock-bit configuration, the WSM continues functioning, and consuming active power until the operation completes.

3.1.5 **Reset/Power-Down**

RP# at VIL initiates the reset/power-down mode.

In read modes, RP#-low deselects the memory, places output drivers in a high-impedance state, and turns off numerous internal circuits. RP# must be held low for a minimum of tPLPH. Time tPHQV is required after return from reset mode until initial memory access outputs are valid. After this wake-up interval, normal operation is restored. The CUI is reset to read array mode and Status Register is set to 0x80.

During block erase, program, or lock-bit configuration modes, RP#-low will abort the operation. In default mode, STS transitions low and remains low for a maximum time of tP PH + tPHRH until the reset operation is complete. Memory contents being altered are no longer valid; the data may be partially corrupted after a program or partially altered after an erase or lock-bit configuration. Time tP H W L is required after RP# goes to logic-high (VIH) before another command can be written.

As with any automated device, it is important to assert RP# during system reset. When the system comes out of reset, it expects to read from the flash memory. Automated flash memories provide status information when accessed during block erase, program, or lock-bit configuration modes. If a CPU reset occurs with no flash memory reset, proper initialization may not occur because the flash memory may be providing status information instead of array data. Intel® Flash memories allow proper initialization following a system reset through the use of the RP# input. In this application, RP# is controlled by the same RESET# signal that resets the system CPU.

### 3.2 Device Commands

When the VPE N voltage ≤ VPE NLK, only read operations from the Status Register, query, identifier codes, or blocks are enabled. Placing VPE NH on VPE NH additionally enables block erase, program, and lock-bit configuration operations. Device operations are selected by writing specific commands into the CUI. Table 4, “Intel StrataFlash® Memory Command Set Definitions” on page 17 defines these commands.

**NOTES:**
1. Commands other than those shown above are reserved by Intel for future device implementations and should not be used.
2. The Basic Command Set (BCS) is the same as the 28F008SA Command Set or Intel Standard Command Set. The Scalable Command Set (SCS) is also referred to as the Intel Extended Command Set.
3. Bus operations are defined in Table 2.
4. X = Any valid address within the device.
5. IA = Identifier within the block.
6. QA = Query database Address.
7. PA = Address of memory location to be programmed.
8. RCD = Data to be read from the read configuration register. This data is presented to the device on A[16:1]; all other address inputs are ignored.
9. ID = Data read from Identifier Codes.
10. QD = Data read from Query database.
11. SRD = Data read from Status Register. See Table 6 for a description of the Status Register bits.
12. PD = Data to be programmed at location PA. Data is latched on the rising edge of WE#.
13. CC = Configuration Code.
14. The write to buffer or erase operation does not begin until a Confirm command (0xD0) is issued.
15. The clear block lock-bits operation simultaneously clears all block lock-bits.
4.0 Read Operations

The device supports four types of read modes: read array, read identifier, read status or read query. Upon power-up or return from reset, the device defaults to read array mode. To change the device’s read mode, the appropriate Read command must be written to the device. (See Section 3.2, “Device Commands” on page 17.) See Section 8.0, “Special Modes” on page 30 for details regarding read status, read ID, and CFI query modes.

Upon initial device power-up or after exit from reset/power-down mode, the device automatically resets to read array mode. Otherwise, write the appropriate read mode command (Read Array, Read Query, Read Identifier Codes, or Read Status Register) to the CUI. Six control signals dictate the data flow in and out of the component: CE0, CE1, CE2, OE#, WE#, and RP#. The device must be enabled (see Table 3, “Chip Enable Truth Table” on page 16), and OE# must be driven active to obtain data at the outputs. CE0, CE1, and CE2 are the device selection controls and, when enabled (see Table 3), select the memory device. OE# is the data output (D[15:0]) control and, when active, drives the selected memory data onto the I/O bus. WE# must be at $V_{IH}$.

4.1 Read Array

Upon initial device power-up and after exit from reset/power-down mode, the device defaults to read array mode. The read configuration register defaults to asynchronous read page mode. The Read Array command also causes the device to enter read array mode. The device remains enabled for reads until another command is written. If the internal WSM has started a block erase, program, or lock-bit configuration, the device will not recognize the Read Array command until the WSM completes its operation unless the WSM is suspended via an Erase or Program Suspend command. The Read Array command functions independently of the $V_{PEN}$ voltage.

4.1.1 Asynchronous Page-Mode Read

Asynchronous Page Mode is the default read mode on power-up or reset. To perform a page mode read after any other operation, the Read Array command must be issued to read from the flash array. Asynchronous page mode reads are permitted in all blocks and is used to access register information, but only one word is loaded into the page buffer during register access. In asynchronous page mode, array data is sensed and loaded into a page buffer. After the initial delay, the first word out of the page buffer corresponds to the initial address.

Address bits A[2:0] determine which word is output from the page buffer. Subsequent reads from the device come from the page buffer, and are output on D[15:0] after a minimum delay as long as address bits A[2:0] are the only address bits that change. Data can be read from the page buffer multiple times, and in any order. If address bits A[MAX:3] change at any time, or if CE# is toggled, the device will sense and load new data into the page buffer.

4.2 Read Identifier Codes

The Read identifier codes operation outputs the manufacturer code, device-code, and the block lock configuration codes for each block (See Figure 3.2 on page 17 for details on issuing the Read Device Identifier command). Page-mode reads are not supported in this read mode. To terminate the operation, write another valid command. Like the Read Array command, the Read Identifier
Codes command functions independently of the \( V_{\text{PEN}} \) voltage. This command is valid only when the WSM is off or the device is suspended. Following the Read Identifier Codes command, the following information can be read.

### 4.3 Read Status Register

The Status Register may be read to determine when a block erase, program, or lock-bit configuration is complete and whether the operation completed successfully. It may be read at any time by writing the Read Status Register command. After writing this command, all subsequent read operations output data from the Status Register until another valid command is written. Page-mode reads are not supported in this read mode. The Status Register contents are latched on the falling edge of OE# or the first edge of CE0, CE1, or CE2 that enables the device (see Table 3, “Chip Enable Truth Table” on page 16). OE# must toggle to \( V_{\text{IH}} \) or the device must be disabled before further reads to update the Status Register latch. The Read Status Register command functions independently of the \( V_{\text{PEN}} \) voltage.

During a program, block erase, set lock-bit, or clear lock-bit command sequence, only SR7 is valid until the Write State Machine completes or suspends the operation. Device I/O signals \( D[6:0] \) and \( D[15:8] \) are placed in a high-impedance state. When the operation completes or suspends (check SR7), all contents of the Status Register are valid when read.

4.4 Read Query/CFI

The query register contains an assortment of flash product information such as block size, density, allowable command sets, electrical specifications and other product information. The data contained in this register conforms to the Common Flash Interface (CFI) protocol. To obtain any information from the query register, execute the Read Query Register command. See Section 3.2, “Device Commands” on page 17 for details on issuing the CFI Query command. Refer to Appendix B, “CFI Descriptions” on page 47 for a detailed explanation of the CFI register. Information contained in this register can only be accessed by executing a single-word read.

5.0 Programming Operations

The device supports two different programming methods: word programming, and write-buffer programming. Successful programming requires the addressed block to be unlocked. An attempt to program a locked block will result in the operation aborting, and SR1 and SR4 being set, indicating a programming error. The following sections describe device programming in detail.

5.1 Byte/Word Program

Byte/Word program is executed by a two-cycle command sequence. Byte/Word program setup (standard 0x40 or alternate 0x10) is written followed by a second write that specifies the address and data (latched on the rising edge of WE#). The WSM then takes over, controlling the program and program verify algorithms internally. After the program sequence is written, the device automatically outputs SRD when read (see Figure 14, “Byte/Word Program Flowchart” on page 55). The CPU can detect the completion of the program event by analyzing the STS signal or SR7.

When program is complete, SR4 should be checked. If a program error is detected, the Status Register should be cleared. The internal WSM verify only detects errors for “1”s that do not successfully program to “0”s. The CUI remains in Read Status Register mode until it receives another command.

Reliable byte/word programming can only occur when $V_{CC}$ and $V_{PEN}$ are valid. If a byte/word program is attempted while $V_{PEN} \leq V_{PENLK}$, SR4 and SR3 will be set. Successful byte/word programs require that the corresponding block lock-bit be cleared. If a byte/word program is attempted when the corresponding block lock-bit is set, SR1 and SR4 will be set.

5.2 Write to Buffer

To program the flash device, a Write to Buffer command sequence is initiated. A variable number of bytes, up to the buffer size, can be loaded into the buffer and written to the flash device. First, the Write to Buffer Setup command is issued along with the Block Address (see Figure 12, “Write to Buffer Flowchart” on page 53). At this point, the eXtended Status Register (XSR, see Table 7) information is loaded and XSR7 reverts to “buffer available” status. If XSR7 = 0, the write buffer is not available. To retry, continue monitoring XSR7 by issuing the Write to Buffer setup command with the Block Address until XSR7 = 1. When XSR7 transitions to a “1,” the buffer is ready for loading.
Now a word/byte count is given to the part with the Block Address. On the next write, a device start address is given along with the write buffer data. Subsequent writes provide additional device addresses and data, depending on the count. All subsequent addresses must lie within the start address plus the count.

Internally, this device programs many flash cells in parallel. Because of this parallel programming, maximum programming performance and lower power are obtained by aligning the start address at the beginning of a write buffer boundary (i.e., $A[4:0]$ of the start address = 0).

After the final buffer data is given, a Write Confirm command is issued. This initiates the WSM (Write State Machine) to begin copying the buffer data to the flash array. If a command other than Write Confirm is written to the device, an “Invalid Command/Sequence” error will be generated and SR5 and SR4 will be set. For additional buffer writes, issue another Write to Buffer Setup command and check XSR7.

If an error occurs while writing, the device will stop writing, and SR4 will be set to indicate a program failure. The internal WSM verify only detects errors for “1”s that do not successfully program to “0”. If a program error is detected, the Status Register should be cleared. Any time SR4 and/or SR5 is set (e.g., a media failure occurs during a program or an erase), the device will not accept any more Write to Buffer commands. Additionally, if the user attempts to program past an erase block boundary with a Write to Buffer command, the device will abort the write to buffer operation. This will generate an “Invalid Command/Sequence” error and SR5 and SR4 will be set.

Reliable buffered writes can only occur when $V_{PEN} = V_{PENH}$. If a buffered write is attempted while $V_{PEN} \leq V_{PENLK}$, SR4 and SR3 will be set. Buffered write attempts with invalid $V_{CC}$ and $V_{PEN}$ voltages produce spurious results and should not be attempted. Finally, successful programming requires that the corresponding block lock-bit be reset. If a buffered write is attempted when the corresponding block lock-bit is set, SR1 and SR4 will be set.

### 5.3 Program Suspend

The Program Suspend command allows program interruption to read data in other flash memory locations. Once the programming process starts (either by initiating a write to buffer or byte/word program operation), writing the Program Suspend command requests that the WSM suspend the program sequence at a predetermined point in the algorithm. The device continues to output SRD when read after the Program Suspend command is written. Polling SR7 can determine when the programming operation has been suspended. When SR7 = 1, SR2 should also be set, indicating that the device is in the program suspend mode. STS in level RY/BY# mode will also transition to $V_{OH}$. Specification $t_{WHRH1}$ defines the program suspend latency.

At this point, a Read Array command can be written to read data from locations other than that which is suspended. The only other valid commands while programming is suspended are Read Query, Read Status Register, Clear Status Register, Configure, and Program Resume. After a Program Resume command is written, the WSM will continue the programming process. SR2 and SR7 will automatically clear and STS in RY/BY# mode will return to $V_{OL}$. After the Program Resume command is written, the device automatically outputs SRD when read. $V_{PEN}$ must remain at $V_{PENH}$ and $V_{CC}$ must remain at valid $V_{CC}$ levels (the same $V_{PEN}$ and $V_{CC}$ levels used for programming) while in program suspend mode. Refer to Figure 15, “Program Suspend/Resume Flowchart” on page 56.
5.4 Program Resume

To resume (i.e., continue) a program suspend operation, execute the Program Resume command. The Resume command can be written to any device address. When a program operation is nested within an erase suspend operation and the Program Suspend command is issued, the device will suspend the program operation. When the Resume command is issued, the device will resume and complete the program operation. Once the nested program operation is completed, an additional Resume command is required to complete the block erase operation. The device supports a maximum suspend/resume of two nested routines. See Figure 15, “Program Suspend/Resume Flowchart” on page 56.

6.0 Erase Operations

Flash erasing is performed on a block basis; therefore, only one block can be erased at a time. Once a block is erased, all bits within that block will read as a logic level one. To determine the status of a block erase, poll the Status Register and analyze the bits. This following section describes block erase operations in detail.

6.1 Block Erase

Erase is executed one block at a time and initiated by a two-cycle command. A block erase setup is first written, followed by an block erase confirm. This command sequence requires an appropriate address within the block to be erased (erase changes all block data to FFH). Block preconditioning, erase, and verify are handled internally by the WSM (invisible to the system). After the two-cycle block erase sequence is written, the device automatically outputs SRD when read (see Figure 16, “Block Erase Flowchart” on page 57). The CPU can detect block erase completion by analyzing the output of the STS signal or SR7. Toggle OE#, CE0, CE1, or CE2 to update the Status Register.

When the block erase is complete, SR5 should be checked. If a block erase error is detected, the Status Register should be cleared before system software attempts corrective actions. The CUI remains in Read Status Register mode until a new command is issued.

This two-step command sequence of setup followed by execution ensures that block contents are not accidentally erased. An invalid Block Erase command sequence will result in both SR4 and SR5 being set. Also, reliable block erasure can only occur when \( V_{CC} \) is valid and \( V_{PEN} \leq V_{PENLK} \). If block erase is attempted while \( V_{PEN} \leq V_{PENLK} \), SR3 and SR5 will be set. Successful block erase requires that the corresponding block lock-bit be cleared. If block erase is attempted when the corresponding block lock-bit is set, SR1 and SR5 will be set.

6.2 Block Erase Suspend

The Block Erase Suspend command allows block-erase interruption to read or program data in another block of memory. Once the block erase process starts, writing the Block Erase Suspend command requests that the WSM suspend the block erase sequence at a predetermined point in the algorithm. The device outputs SRD when read after the Block Erase Suspend command is written. Polling SR7 then SR6 can determine when the block erase operation has been suspended (both will be set). In default mode, STS will also transition to \( V_{OH} \). Specification \( t_{WHRH} \) defines the block erase suspend latency.
At this point, a Read Array command can be written to read data from blocks other than that which is suspended. A program command sequence can also be issued during erase suspend to program data in other blocks. During a program operation with block erase suspended, SR7 will return to “0” and STS output (in default mode) will transition to V_OL. However, SR6 will remain “1” to indicate block erase suspend status. Using the Program Suspend command, a program operation can also be suspended. Resuming a suspended programming operation by issuing the Program Resume command allows continuing of the suspended programming operation. To resume the suspended erase, the user must wait for the programming operation to complete before issuing the Block Erase Resume command.

The only other valid commands while block erase is suspended are Read Query, Read Status Register, Clear Status Register, Configure, and Block Erase Resume. After a Block Erase Resume command is written to the flash memory, the WSM will continue the block erase process. SR6 and SR7 will automatically clear and STS (in default mode) will return to V_OL. After the Erase Resume command is written, the device automatically outputs SRD when read (see Figure 17, “Block Erase Suspend/Resume Flowchart” on page 58). VPEN must remain at VPENH (the same VPEN level used for block erase) while block erase is suspended. Block erase cannot resume until program operations initiated during block erase suspend have completed.

6.3 Erase Resume

To resume (i.e., continue) an erase suspend operation, execute the Erase Resume command. The Resume command can be written to any device address. When a program operation is nested within an erase suspend operation and the Program Suspend command is issued, the device will suspend the program operation. When the Resume command is issued, the device will resume the program operations first. Once the nested program operation is completed, an additional Resume command is required to complete the block erase operation. The device supports a maximum suspend/resume of two nested routines. See Figure 16, “Block Erase Flowchart” on page 57.
7.0 Security Modes

This device offers both hardware and software security features. Block lock operations, PRs, and VPEN allow the user to implement various levels of data protection. The following section describes security features in detail.

7.1 Set Block Lock-Bit

A flexible block locking scheme is enabled via block lock-bits. The block lock-bits gate program and erase operations. Individual block lock-bits can be set using the Set Block Lock-Bit command. This command is invalid while the WSM is running or the device is suspended.

Set block lock-bit commands are executed by a two-cycle sequence. The set block setup along with appropriate block address is followed by either the set block lock-bit confirm (and an address within the block to be locked). The WSM then controls the set lock-bit algorithm. After the sequence is written, the device automatically outputs Status Register data when read (see Figure 18 on page 59). The CPU can detect the completion of the set lock-bit event by analyzing the STS signal output or SR7.

When the set lock-bit operation is complete, SR4 should be checked. If an error is detected, the Status Register should be cleared. The CUI will remain in Read Status Register mode until a new command is issued.

This two-step sequence of setup followed by execution ensures that lock-bits are not accidentally set. An invalid Set Block Lock-Bit command will result in SR4 and SR5 being set. Also, reliable operations occur only when V<sub>CC</sub> and V<sub> PEN</sub> are valid. With V<sub>PEN</sub> ≤ V<sub>PENLK</sub>, lock-bit contents are protected against alteration.

7.2 Clear Block Lock-Bits

All set block lock-bits are cleared in parallel via the Clear Block Lock-Bits command. Block lock-bits can be cleared using only the Clear Block Lock-Bits command. This command is invalid while the WSM is running or the device is suspended.

Clear block lock-bits command is executed by a two-cycle sequence. A clear block lock-bits setup is first written. The device automatically outputs Status Register data when read (see Figure 19 on page 60). The CPU can detect completion of the clear block lock-bits event by analyzing the STS signal output or SR7.

When the operation is complete, SR5 should be checked. If a clear block lock-bit error is detected, the Status Register should be cleared. The CUI will remain in Read Status Register mode until another command is issued.

This two-step sequence of setup followed by execution ensures that block lock-bits are not accidentally cleared. An invalid Clear Block Lock-Bits command sequence will result in SR4 and SR5 being set. Also, a reliable clear block lock-bits operation can only occur when V<sub>CC</sub> and V<sub>PEN</sub> are valid. If a clear block lock-bits operation is attempted while V<sub>PEN</sub> ≤ V<sub>PENLK</sub>, SR3 and SR5 will be set.
If a clear block lock-bits operation is aborted due to $V_{\text{PEN}}$ or $V_{\text{CC}}$ transitioning out of valid range, block lock-bit values are left in an undetermined state. A repeat of clear block lock-bits is required to initialize block lock-bit contents to known values.

### 7.3 Protection Register Program

The 3 Volt Intel StrataFlash® memory includes a 128-bit Protection Register that can be used to increase the security of a system design. For example, the number contained in the PR can be used to “mate” the flash component with other system components such as the CPU or ASIC, preventing device substitution.

The 128-bits of the PR are divided into two 64-bit segments. One of the segments is programmed at the Intel factory with a unique 64-bit number, which is unalterable. The other segment is left blank for customer designers to program as desired. Once the customer segment is programmed, it can be locked to prevent further programming.

#### 7.3.1 Reading the Protection Register

The Protection Register is read in the identification read mode. The device is switched to this mode by issuing the Read Identifier command (0x90). Once in this mode, read cycles from addresses shown in Table 8 or Table 9 retrieve the specified information. To return to read array mode, write the Read Array command (0xFF).

#### 7.3.2 Programming the Protection Register

Protection Register bits are programmed using the two-cycle Protection Program command. The 64-bit number is programmed 16 bits at a time for word-wide configuration and eight bits at a time for byte-wide configuration. First write the Protection Program Setup command, 0xC0. The next write to the device will latch in address and data and program the specified location. The allowable addresses are shown in Table 8 or Table 9. See Figure 20, “Protection Register Programming Flowchart” on page 61

Any attempt to address Protection Program commands outside the defined PR address space will result in a Status Register error (SR4 will be set). Attempting to program a locked PR segment will result in a Status Register error (SR4 and SR1 will be set).

#### 7.3.3 Locking the Protection Register

The user-programmable segment of the Protection Register is lockable by programming Bit 1 of the PLR to 0. Bit 0 of this location is programmed to 0 at the Intel factory to protect the unique device number. Bit 1 is set using the Protection Program command to program “0xFFFFD” to the PLR. After these bits have been programmed, no further changes can be made to the values stored in the protection register. Protection Program commands to a locked section will result in a Status Register error (SR4 and SR1 will be set). PR lockout state is not reversible.
Figure 6. Protection Register Memory Map

NOTE: A0 is not used in x16 mode when accessing the protection register map (See Table 8 for x16 addressing). For x8 mode A0 is used (See Table 9 for x8 addressing).

</table>

**NOTE:** All address lines not specified in the above table must be 0 when accessing the Protection Register, i.e., A[MAX:9] = 0.
7.4 **Array Protection**

The \( V_{\text{PEN}} \) signal is a hardware mechanism to prohibit array alteration. When the \( V_{\text{PEN}} \) voltage is below the \( V_{\text{PENLK}} \) voltage, array contents cannot be altered. To ensure a proper erase or program operation, \( V_{\text{PEN}} \) must be set to a valid voltage level. To determine the status of an erase or program operation, poll the Status Register and analyze the bits.

8.0 **Special Modes**

This section describes how to read the status, ID, and CFI registers. This section also details how to configure the STS signal.

8.1 **Set Read Configuration**

This command is not supported on this product. This device will default to the asynchronous page mode. If this command is given to the device, it will not affect the operation of the device.

8.1.1 **Read Configuration**

The device will support both asynchronous page mode and standard word/byte reads. No configuration is required.

Status Register and identifier only support standard word/byte single read operations.

<table>
<thead>
<tr>
<th>Table 10. Read Configuration Register Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>R</td>
</tr>
<tr>
<td>---</td>
</tr>
<tr>
<td>16 (A16)</td>
</tr>
<tr>
<td>R</td>
</tr>
<tr>
<td>8</td>
</tr>
</tbody>
</table>

**Notes**

- **RCR.16 = READ MODE (RM)**
  - 0 = Standard Word/Byte Reads Enabled (Default)
  - 1 = Page-Mode Reads Enabled
  
  Read mode configuration effects reads from the flash array. Status Register, query, and identifier reads support standard word/byte read cycles.

- **RCR.15–1 = RESERVED FOR FUTURE ENHANCEMENTS (R)**
  
  These bits are reserved for future use. Set these bits to “0.”

8.2 **STS**

The Status (STS) signal can be configured to different states using the Configuration command. Once the STS signal has been configured, it remains in that configuration until another configuration command is issued or RP# is asserted low. Initially, the STS signal defaults to RY/BY# operation where RY/BY# low indicates that the WSM is busy. RY/BY# high indicates that the state machine is ready for a new operation or suspended. Table 11, “Configuration Coding Definitions” on page 32 displays the possible STS configurations.
To reconfigure the Status (STS) signal to other modes, the Configuration command is given followed by the desired configuration code. The three alternate configurations are all pulse mode for use as a system interrupt as described below. For these configurations, bit 0 controls Erase Complete interrupt pulse, and bit 1 controls Program Complete interrupt pulse. Supplying the 0x00 configuration code with the Configuration command resets the STS signal to the default RY/BY# level mode. The possible configurations and their usage are described in Table 11, “Configuration Coding Definitions” on page 32. The Configuration command may only be given when the device is not busy or suspended. Check SR7 for device status. An invalid configuration code will result in both SR4 and SR5 being set. When configured in one of the pulse modes, the STS signal pulses low with a typical pulse width of 250 ns.

</table>

### NOTES:

1. When configured in one of the pulse modes, STS pulses low with a typical pulse width of 250 ns.
2. An invalid configuration code will result in both SR4 and SR5 being set.
9.0 Power and Reset

This section provides an overview of some system level considerations in regards to the flash device. This section provides a brief description of power-up, power-down, decoupling and reset design considerations.

9.1 Power-Up/Down Characteristics

In order to prevent any condition that may result in a spurious write or erase operation, it is recommended to power-up and power-down VCC and VCCQ together. It is also recommended to power-up VPEN with or slightly after VCC. Conversely, VPEN must power down with or slightly before VCC.

9.2 Power Supply Decoupling

When the device is enabled, many internal conditions change. Circuits are energized, charge pumps are switched on, and internal voltage nodes are ramped. All of this internal activities produce transient signals. The magnitude of the transient signals depends on the device and system loading. To minimize the effect of these transient signals, a 0.1 µF ceramic capacitor is required across each VCC/VSS and VCCQ signal. Capacitors should be placed as close as possible to device connections.

Additionally, for every eight flash devices, a 4.7 µF electrolytic capacitor should be placed between VCC and VSS at the power supply connection. This 4.7 µF capacitor should help overcome voltage slumps caused by PCB (printed circuit board) trace inductance.

9.3 Reset Characteristics

By holding the flash device in reset during power-up and power-down transitions, invalid bus conditions may be masked. The flash device enters reset mode when RP# is driven low. In reset, internal flash circuitry is disabled and outputs are placed in a high-impedance state. After return from reset, a certain amount of time is required before the flash device is able to perform normal operations. After return from reset, the flash device defaults to asynchronous page mode. If RP# is driven low during a program or erase operation, the program or erase operation will be aborted and the memory contents at the aborted block or address are no longer valid. See Figure 19, “Reset Operation Waveforms” on page 50 for detailed information regarding reset timings.
10.0 Electrical Specifications

10.1 Absolute Maximum Ratings

This datasheet contains information on new products in production. The specifications are subject to change without notice. Verify with your local Intel Sales office that you have the latest datasheet before finalizing a design. Absolute maximum ratings are shown in Table 12.

**Warning:** Stressing the device beyond the “Absolute Maximum Ratings” may cause permanent damage. These are stress ratings only. Operation beyond the “Operating Conditions” is not recommended and extended exposure beyond the “Operating Conditions” may affect device reliability.

**Table 12. Absolute Maximum Ratings**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Maximum Rating</th>
</tr>
</thead>
<tbody>
<tr>
<td>Temperature under Bias Extended</td>
<td>–40 °C to +85 °C</td>
</tr>
<tr>
<td>Storage Temperature</td>
<td>–65 °C to +125 °C</td>
</tr>
<tr>
<td>Voltage On Any signal</td>
<td>–2.0 V to +5.0 V(1)</td>
</tr>
<tr>
<td>Output Short Circuit Current</td>
<td>100 mA(2)</td>
</tr>
</tbody>
</table>

**NOTES:**
1. All specified voltages are with respect to GND. Minimum DC voltage is –0.5 V on input/output signals and –0.2 V on VCC and VPEN signals. During transitions, this level may undershoot to –2.0 V for periods <20 ns. Maximum DC voltage on input/output signals, VCC, and VPEN is VCC +0.5 V which, during transitions, may overshoot to VCC +2.0 V for periods <20 ns.
2. Output shorted for no more than one second. No more than one output shorted at a time.

</tbody>
</table>

**NOTES:**

- CE\(X\) low is defined as the first edge of CE0, CE1, or CE2 that enables the device. CE\(X\) high is defined at the first edge of CE0, CE1, or CE2 that disables the device (see Table 3).
- OE# may be delayed up to \(t_{ELQV} + t_{GLQV}\) after the first edge of CE0, CE1, or CE2 that enables the device (see Table 3) without impact on \(t_{ELQV}\).
- See Figure 10, "Transient Input/Output Reference Waveform for VCCQ = 2.7 V–3.6 V" on page 42 and Figure 11, "Transient Equivalent Testing Load Circuit" on page 43 for testing characteristics.
- When reading the flash array a faster \(t_{GLQV}\) (R16) applies. Non-array reads refer to Status Register reads, query reads, or device identifier reads.
- Sampled, not 100% tested.
- For devices configured to standard word/byte read mode, R15 \(t_{APA}\) will equal R2 \(t_{AVQV}\).

**Figure 7. AC Waveform for Both Page-Mode and Standard Word/Byte Read Operations**

**NOTE:** CE\(X\) low is defined as the first edge of CE0, CE1, or CE2 that enables the device. CE\(X\) high is defined at the first edge of CE0, CE1, or CE2 that disables the device (see Table 3). For standard word/byte read operations, R15 \(t_{APA}\) will equal R2 \(t_{AVQV}\). When reading the flash array a faster \(t_{GLQV}\) (R16) applies. Non-array reads refer to Status Register reads, query reads, or device identifier reads.

</tbody>
</table>

NOTES:
- CEX low is defined as the first edge of CE0, CE1, or CE2 that enables the device. CEX high is defined as the first edge of CE0, CE1, or CE2 that disables the device (see Table 3).
- Read timing characteristics during block erase, program, and lock-bit configuration operations are the same as during read-only operations. Refer to AC Characteristics–Read-Only Operations.
- A write operation can be initiated and terminated with either CEX or WE#.
- Sampled, not 100% tested.
- Write pulse width (tWP) is defined from CEX or WE# going low (whichever goes low last) to CEX or WE# going high (whichever goes high first). Hence, tWP = tWLWH = tELEH = tWLEH = tELWH.
- Refer to Table 4 for valid Ain and Din for block erase, program, or lock-bit configuration.
- Write pulse width high (tWPH) is defined from CEX or WE# going high (whichever goes high first) to CEX or WE# going low (whichever goes low first). Hence, tWPH = tWHHL = tHEHL = tWHEL = tELWH.
- For array access, tAvQV is required in addition to tWHQL for any accesses after a write.
- STS timings are based on STS configured in its RY/BY# default mode.
- V_PEN should be held at V_PENH until determination of block erase, program, or lock-bit configuration success (SR[1,3,4:5] = 0).
### 11.3 Block Erase, Program, and Lock-Bit Configuration Performance

</tbody>
</table>

NOTES:
1. Typical values measured at \( T_A = +25 \, ^\circ\text{C} \) and nominal voltages. Assumes corresponding lock-bits are not set. Subject to change based on device characterization.
2. These performance numbers are valid for all speed versions.
3. Sampled but not 100% tested.
4. Excludes system-level overhead.
5. These values are valid when the buffer is full, and the start address is aligned on a 32-byte boundary.
6. Effective per-byte program time (\( t_{WHQV1}, t_{EHQV1} \)) is 6.8 µs/byte (typical).
7. Effective per-word program time (\( t_{WHQV2}, t_{EHQV2} \)) is 13.6 µs/word (typical).
8. Max values are measured at worst case temperature and \( V_{CC} \) corner after 100k cycles (except as noted).
9. Max values are expressed at -25 °C/-40 °C.
10. Max values are expressed at 25 °C/-40 °C.
NOTES:
CE<sub>X</sub> low is defined as the first edge of CE0, CE1, or CE2 that enables the device. CE<sub>X</sub> high is defined at the first edge of CE0, CE1, or CE2 that disables the device (see Table 3).
STS is shown in its default mode (RY/BY#).
- a. V<sub>CC</sub> power-up and standby.
- b. Write block erase, write buffer, or program setup.
- c. Write block erase or write buffer confirm, or valid address and data.
- d. Automated erase delay.
- e. Read Status Register or query data.
- f. Write Read Array command.
### 11.4 Reset Operation

Figure 9. AC Waveform for Reset Operation

![AC Waveform for Reset Operation](image)

NOTE: STS is shown in its default mode (RY/BY#).

#### Table 19. Reset Specifications

<table>
<thead>
<tr>
<th>#</th>
<th>Sym</th>
<th>Parameter</th>
<th>Min</th>
<th>Max</th>
<th>Unit</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>P1</td>
<td>$t_{\text{PLPH}}$</td>

<td>RP# High to Reset during Block Erase, Program, or Lock-Bit Configuration</td>
<td>100</td>
<td></td>
<td>ns</td>
<td>1, 3</td>
</tr>
</tbody>
</table>

NOTES:
1. These specifications are valid for all product versions (packages and speeds).
2. If RP# is asserted while a block erase, program, or lock-bit configuration operation is not executing then the minimum required RP# Pulse Low Time is 100 ns.
3. A reset time, $t_{\text{PHQV}}$, is required from the latter of STS (in RY/BY# mode) or RP# going high until outputs are valid.

### 11.5 AC Test Conditions

Figure 10. Transient Input/Output Reference Waveform for $V_{\text{CCQ}} = 2.7$ V–3.6 V

![Transient Input/Output Reference Waveform](image)

NOTE: AC test inputs are driven at $V_{\text{CCQ}}$ for a Logic "1" and 0.0 V for a Logic "0." Input timing begins, and output timing ends, at $V_{\text{CCQ}}/2$ V (50% of $V_{\text{CCQ}}$). Input rise and fall times (10% to 90%) < 5 ns.

NOTES:
1. Sampled, not 100% tested.
Appendix A  Write State Machine (WSM)

A.1  TBD
Appendix B  Common Flash Interface

The Common Flash Interface (CFI) specification outlines device and host system software interrogation handshake which allows specific vendor-specified software algorithms to be used for entire families of devices. This allows device independent, JEDEC ID-independent, and forward- and backward-compatible software support for the specified flash device families. It allows flash vendors to standardize their existing interfaces for long-term compatibility.

This appendix defines the data structure or “database” returned by the Common Flash Interface (CFI) Query command. System software should parse this structure to gain critical information such as block size, density, x8/x16, and electrical specifications. Once this information has been obtained, the software will know which command sets to use to enable flash writes, block erases, and otherwise control the flash component. The Query is part of an overall specification for multiple command set and control interface descriptions called Common Flash Interface, or CFI.

B.1  Query Structure Output

The Query “database” allows system software to gain information for controlling the flash component. This section describes the device’s CFI-compliant interface that allows the host system to access Query data.

Query data are always presented on the lowest-order data outputs (D[7:0]) only. The numerical offset value is the address relative to the maximum bus width supported by the device. On this family of devices, the Query table device starting address is a 10h, which is a word address for x16 devices.

For a word-wide (x16) device, the first two bytes of the Query structure, “Q” and “R” in ASCII, appear on the low byte at word addresses 10h and 11h. This CFI-compliant device outputs 00H data on upper bytes. Thus, the device outputs ASCII “Q” in the low byte (D[7:0]) and 00H in the high byte (D[15:8]).

At Query addresses containing two or more bytes of information, the least significant data byte is presented at the lower address, and the most significant data byte is presented at the higher address.

In all of the following tables, addresses and data are represented in hexadecimal notation, so the “h” suffix has been dropped. In addition, since the upper byte of word-wide devices is always “00h,” the leading “00” has been dropped from the table notation and only the lower byte value is shown. Any x16 device outputs can be assumed to have 00h on the upper byte in this mode.
Table 20. Summary of Query Structure Output as a Function of Device and Mode

<table>
<thead>
<tr>
<th>Device Type/Mode</th>
<th>Query start location in maximum device bus width addresses</th>
<th>Query data with maximum device bus width addressing</th>
<th>Query data with byte addressing</th>
</tr>
</thead>
<tbody>
<tr>
<td>x16 device x16 mode</td>
<td>10h</td>
<td>Hex Offset</td>
<td>Hex Code</td>
</tr>
<tr>
<td></td>
<td></td>
<td>10:</td>
<td>0051</td>
</tr>
<tr>
<td></td>
<td></td>
<td>11:</td>
<td>0052</td>
</tr>
<tr>
<td></td>
<td></td>
<td>12:</td>
<td>0059</td>
</tr>
<tr>

<tr>
<td></td>
<td></td>
<td>20:</td>
<td>51</td>
</tr>
<tr>
<td></td>
<td></td>
<td>22:</td>
<td>52</td>
</tr>
</tbody>
</table>

NOTE:
1. The system must drive the lowest order addresses to access all the device’s array data when the device is configured in x8 mode. Therefore, word addressing, where these lower addresses are not toggled by the system, is "Not Applicable" for x8-configured devices.

B.2 Query Structure Overview

The Query command causes the flash component to display the Common Flash Interface (CFI) Query structure or “database.” The structure sub-sections and address locations are summarized below. See AP-646 Common Flash Interface (CFI) and Command Sets (order number 292204) for a full description of CFI.

The following sections describe the Query structure sub-sections in detail.
Table 22. Query Structure

<table>
<thead>
<tr>

<td>1</td>
</tr>
<tr>
<td>p(3)</td>
<td>Primary Intel-Specific Extended Query Table</td>
<td>Vendor-Defined Additional Information Specific to the Primary Vendor Algorithm</td>
<td>1,3</td>
</tr>
</tbody>
</table>

NOTES:
1. Refer to the Query Structure Output section and offset 28h for the detailed definition of offset address as a function of device bus width and mode.
2. BA = Block Address beginning location (i.e., 02000h is block 2’s beginning location when the block size is 128 Kbyte).
3. Offset 15 defines “P” which points to the Primary Intel-Specific Extended Query Table.

B.3 Block Status Register

The block status register indicates whether an erase operation completed successfully or whether a given block is locked or can be accessed for flash program/erase operations.

Table 23. Block Status Register

<table>
<thead>
<tr>
<th>Offset</th>
<th>Length</th>

<tr>
<td>BSR 1–7</td>
<td></td>
<td>Reserved for Future Use</td>
<td>BA+2:</td>
<td>(bit 1–7): 0</td>
</tr>
</tbody>
</table>

NOTE:  
1. BA = The beginning location of a Block Address (i.e., 008000h is block 1’s (64-KB block) beginning location in word mode).

B.4 CFI Query Identification String

The CFI Query Identification String provides verification that the component supports the Common Flash Interface specification. It also indicates the specification version and supported vendor-specified command set(s).

Table 24. CFI Identification (Sheet 1 of 2)

Appendix C Flow Charts

Figure 12. Write to Buffer Flowchart

Start

Command Cycle
- Issue Write-to-Buffer Command
- Address = Any address in block
- Data = 0xE8

Check Ready Status
- Read Status Register Command not required
- Perform read operation
- Read Ready Status on signal D7

D7 = 1?

Write Word Count
- Address = Any address in block
- Data = word count
- Valid range = 0x0 thru 0x1F

Write Buffer Data
- Fill write buffer up to word count
- Address = Address(es) within buffer range
- Data = Data to be written

Confirm Cycle
- Issue Confirm Command
- Address = Any address in block
- Data = 0xD0

Read Status Register
See Status Register Flowchart

Any Errors?

Write to Buffer Time-Out?

Write to Buffer Data

Error-Handler
User-defined routine

End
Figure 13. Status Register Flowchart

Command Cycle
- Issue Status Register Command
  - Address = any device address
  - Data = 0x70

Data Cycle
- Read Status Register SR[7:0]

- Set/Reset by WSM
- Set by WSM
- Reset by user
- See Clear Status Register Command

SR7 = '1'  
SR2 = '1'  
SR4 = '1'  
SR1 = '1'  
SR6 = '1'  
SR5 = '1'

End
Figure 14. Byte/Word Program Flowchart

**FULL STATUS CHECK PROCEDURE**

1. Toggling OE# (low to high to low) updates the status register. This can be done in place of issuing the Read Status Register command. Repeat for subsequent programming operations.
2. SR full status check can be done after each program operation, or after a sequence of programming operations.
3. Write FFH after the last program operation to place device in read array mode.

### Bus Operation | Command | Comments
--- | --- | ---
Write | Setup Byte/Word Program | Data = 40H
Write | Byte/Word Program | Data = Data to Be Programmed
Read (Note 1) | Status Register Data | 1. WSM Ready
Standby | Check SR.7 | 0 = WSM Busy

**Command**

<table>
<thead>
<tr>
<th>Data</th>
<th>Addr</th>
</tr>
</thead>
<tbody>
<tr>
<td>40H</td>
<td>Location to Be Programmed</td>
</tr>
<tr>
<td>Data to Be Programmed</td>
<td>Location to Be Programmed</td>
</tr>
</tbody>
</table>

**Notes**

1. SR.4, SR.3 and SR.1 are only cleared by the Clear Status Register command in cases where multiple locations are programmed before full status is checked.
2. If an error is detected, clear the status register before attempting retry or other error recovery.
Figure 15. Program Suspend/Resume Flowchart

Bus Operation | Command | Comments |
-------------|---------|----------|
Write        | Program Suspend | Data = B0H<br>Addr = X |
Read         | Status Register Data<br>Addr = X |
Standby      | Check SR.7<br>1 = WSM Ready<br>0 = WSM Busy |

<td></td>
<td>Check SR.4, 5</td>
<td>Both 1 = Command Sequence Error</td>
</tr>
<tr>
<td>Standby</td>
<td>Check SR.5</td>
<td>1 = Clear Block Lock-Bits Error</td>
</tr>
</tbody>
</table>

SR.5, SR.4, and SR.3 are only cleared by the Clear Status Register command.

If an error is detected, clear the status register before attempting retry or other error recovery.
Protection Register Programming Flowchart

**Figure 20. Protection Register Programming Flowchart**

1. **Start**
2. **Write C0H** (Protection Reg. Program Setup)
3. **Write Protect. Register Address/Data**
4. **Read Status Register**
   - **SR.7 = 1?**
     - **No**
     - **Yes**
5. **Full Status Check if Desired**
6. **Program Complete**

**FULL STATUS CHECK PROCEDURE**

- **Read Status Register Data (See Above)**
  - **SR.3, SR.4 = 1, 1**
    - **V_{FB}** Range Error
  - **SR.3, SR.4 = 0, 1**
    - Protection Register Programming Error
  - **SR.1, SR.4 = 1, 1**
    - Attempted Program to Locked Register - Aborted
  - **SR.1, SR.4 = 0, 1**
    - Program Successful

**Bus Operation** | **Command** | **Comments**
--- | --- | ---
**Write** | Protection Program Setup | Data = C0H
**Write** | Protection Program | Data = Data to Program Addr = Location to Program
**Read** | Status Register Data Toggle CE# or OER to Update Status Register Data
**Standby** | Check SR.7 1 = WSM Ready 0 = WSM Busy

Protection Program operations can only be addressed within the protection register address space. Addresses outside the defined space will return an error.

Repeat for subsequent programming operations.

SR Full Status Check can be done after each program or after a sequence of program operations.

Write FFH after the last program operation to reset device to read array mode.

**Bus Operation** | **Command** | **Comments**
--- | --- | ---
**Standby** | SR.1 SR.3 SR.4 0 1 1 V_{FB} Low
**Standby** | 0 0 1 Prot. Reg. Prog. Error
**Standby** | 1 0 1 Register Locked Aborted

SR.3 MUST be cleared, if set during a program attempt, before further attempts are allowed by the Write State Machine.

SR.1, SR.3 and SR.4 are only cleared by the Clear Status Register Command. In cases of multiple protection register program operations before full status is checked.

If an error is detected, clear the status register before attempting retry or other error recovery.

NOTES:
1. For Daisy Chain Evaluation Unit information refer to the Intel Flash Memory Packaging Technology Web page at: www.intel.com/design/packtech/index.htm
2. For Packaging Shipping Media information refer to the Intel Flash Memory Packaging Technology Web page at: www.intel.com/design/packtech/index.htm
Appendix E  Design Considerations

E.1 Three-Line Output Control

The device will often be used in large memory arrays. Intel provides five control inputs (CE0, CE1, CE2, OE#, and RP#) to accommodate multiple memory connections. This control provides for:

- Lowest possible memory power dissipation.
- Complete assurance that data bus contention will not occur.

To use these control inputs efficiently, an address decoder should enable the device (see Table 3) while OE# should be connected to all memory devices and the system’s READ# control line. This assures that only selected memory devices have active outputs while de-selected memory devices are in standby mode. RP# should be connected to the system POWERGOOD signal to prevent unintended writes during system power transitions. POWERGOOD should also toggle during system reset.

E.2 STS and Block Erase, Program, and Lock-Bit Configuration Polling

STS is an open drain output that should be connected to VCCQ by a pull-up resistor to provide a hardware method of detecting block erase, program, and lock-bit configuration completion. It is recommended that a 2.5k resistor be used between STS# and VCCQ. In default mode, it transitions low after block erase, program, or lock-bit configuration commands and returns to High Z when the WSM has finished executing the internal algorithm. For alternate configurations of the STS signal, see the Configuration command.

STS can be connected to an interrupt input of the system CPU or controller. It is active at all times. STS, in default mode, is also High Z when the device is in block erase suspend (with programming inactive), program suspend, or in reset/power-down mode.

E.3 Input Signal Transitions—Reducing Overshoots and Undershoots When Using Buffers or Transceivers

As faster, high-drive devices such as transceivers or buffers drive input signals to flash memory devices, overshoots and undershoots can sometimes cause input signals to exceed flash memory specifications. (See “Absolute Maximum Ratings” on page 33.) Many buffer/transceiver vendors now carry bus-interface devices with internal output-damping resistors or reduced-drive outputs. Internal output-damping resistors diminish the nominal output drive currents, while still leaving sufficient drive capability for most applications. These internal output-damping resistors help reduce unnecessary overshoots and undershoots. Transceivers or buffers with balanced- or light-drive outputs also reduce overshoots and undershoots by diminishing output-drive currents. When considering a buffer/transceiver interface design to flash, devices with internal output-damping resistors or reduced-drive outputs should be used to minimize overshoots and undershoots. For additional information, please refer to AP-647, 5 Volt Intel StrataFlash® Memory Design Guide (Order Number: 292205).
E.4 \( V_{CC}, V_{PEN}, RP# \) Transitions

Block erase, program, and lock-bit configuration are not guaranteed if \( V_{PEN} \) or \( V_{CC} \) falls outside of the specified operating ranges, or \( RP# \neq V_{IH} \). If \( RP# \) transitions to \( V_{IL} \) during block erase, program, or lock-bit configuration, STS (in default mode) will remain low for a maximum time of \( t_{PLPH} + t_{PHRH} \) until the reset operation is complete. Then, the operation will abort and the device will enter reset/power-down mode. The aborted operation may leave data partially corrupted after programming, or partially altered after an erase or lock-bit configuration. Therefore, block erase and lock-bit configuration commands must be repeated after normal operation is restored. Device power-off or \( RP# = V_{IL} \) clears the Status Register.

The CUI latches commands issued by system software and is not altered by \( V_{PEN}, CE_0, CE_1, \) or \( CE_2 \) transitions, or WSM actions. Its state is read array mode upon power-up, after exit from reset/power-down mode, or after \( V_{CC} \) transitions below \( V_{LKO} \). \( V_{CC} \) must be kept at or above \( V_{PEN} \) during \( V_{CC} \) transitions.

After block erase, program, or lock-bit configuration, even after \( V_{PEN} \) transitions down to \( V_{PENLK} \), the CUI must be placed in read array mode via the Read Array command if subsequent access to the memory array is desired. \( V_{PEN} \) must be kept at or below \( V_{CC} \) during \( V_{PEN} \) transitions.

E.5 Power Dissipation

When designing portable systems, designers must consider battery power consumption not only during device operation, but also for data retention during system idle time. Flash memory’s nonvolatility increases usable battery life because data is retained when system power is removed.
